THESE DATA SETS HAVE BEEN RESTORED. ORIGINALLY THERE WERE 19 7-TRACK, 800 BPI TAPES WRITTEN IN BINARY CONTAINING VARIABLE DATA FILES. THERE ARE TWO DIFFERENT KINDS OF DATA, RUN DATA WHICH ARE DESIGNED BY A 'Z' IN THE BEGINNING OF EVERY 80 CHARACTER LOGICAL RECORD AND SHOT DATA WHICH ARE DESIGNATED BY A 'P' IN THE BEGINNING OF EVERY 80 CHARACTER LOGICAL RECORD. THE ORIGINAL TAPES WERE BLOCKED AT 64 LOGICAL RECORDS PER PHYSICAL RECORD. EACH PHYSICAL RECORD HAS AN ADDITIONAL FOUR (4) CHARACTERS AFTER BEING DUPED ON THE 7094 COMPUTER.

THERE IS ONE RESTORED TAPE, THE DR TAPE IS A 3480 CARTRIDGE AND THE DS TAPES IS 9-TRACK, 6250 BPI. THE ORIGINAL TAPES WERE CREATED ON A CDC 6600 COMPUTER.

U = UNFILTERED

69-059C-04C
71-008C-09A
71-063C-08A

Run Card

Read a run card with, for example, the FORTRAN statements

READ (X,1) (A(J),J=1,22)

1 FORMAT(A1,3I,D10.3,1X,I7,I3,3I2,3X,I3,I5,5I3,A5,2I3,2I4,2I2)

ignoring for the moment that we have mixed our variable modes.

Then the variables A will contain the following information:

A(1)	=Z
A(2)	=711 (3-digit observatory code)
A(3)	Julian date of beginning of run
A(4)	Clock epoch error, sec x 10 ⁶
A(5)	Ambient temperature, °C
A(6)	Ambient relative humidity, % saturation
A(7)	Wind speed, km/hr
A(8)	Atmospheric seeing, arc sec x 10
A(9)	laser energy, joules x 10
A(10)	laser frequency, Hz x 10 ¹⁰
A(11)	pulse length, sec x 10 ¹⁰
A(12)	observational resolution, sec x 10 ¹⁰
A(13)	photomultiplier dark count, kHz
A(14)	Moon count rate, kHz (Gross)
A(15)	Star count rate, kHz (Net)
A(16)	Calibration star identification
A(17)	Filter spectral width, Å x 10
A(18)	Filter spatial width, arc sec x 10
A(19)	Number of shots fired this run
A(20)	Year
A(21)	Month-
A(22)	Day-

The sense of the clock error is that it is to be subtracted from the clock time to give the true UTC time. This correction has not been applied to the observation epochs on the shot cards.

Shot Card

Similarly, again ignoring variable mode questions for the sake of illustration, read a shot card with

READ(X,2) (B(J),J=1,17)

2 FORMAT(A1,I3,D17.10,I5,1X,I1,A1,I1,D12.10,I5,I6,I5,3X,I5,I1,
I5,I4,2I2)

Then the variables B will contain the following information:

B(1)	=P
B(2)	=011 (body identifier)
B(3)	Julian date of observation
B(4)	=71110 (observatory code)
B(5)	=0 (reflector code for Tranquility)
B(6)	=L (observation type)
B(7)	=1 (epoch time base is UTC)
B(8)	Observed time delay, seconds
B(9)	Observational uncertainty, seconds $\times 10^{10}$
B(10)	Electronic calibration delay, seconds $\times 10^{10}$
B(11)	Geometric delay, seconds $\times 10^{10}$
B(12)	Clock frequency offset from UTC, parts in 10^{11}
B(13)	=1 (time delay time base is UTC)
B(14)	Ambient pressure, mbar $\times 10$
B(15)	Year
B(16)	Month
B(17)	Day

The electronic and geometric delays refer to the equipment response times and the reduction to the geometric fixed point, respectively, and are to be subtracted from the observed time delay.

A word of warning is in order to the unwary users. During the report interval, many of the specified data items discussed above are not available. In the card images, a blank field is a "no information" indicator. Actual null values will be represented by zero punches. This is particularly important for clock epoch error. No clock data are presently available, although Currie (1970) estimates that the "actual epoch should be known to the order of 10 μ sec or better."

IV. Acknowledgements

The data described herein were generated at the McDonald Observatory through the collective efforts of the LURE Team and numerous supporting personnel at their several institutions.

5. COSPAR WORKING GROUPS

PROPOSED STANDARDS FOR DISTRIBUTION AND DOCUMENTATION OF LUNAR LASER RANGING DATA

A Report prepared for COSPAR Working Group 1

by J. Derral Mulholland, University of Texas at Austin, McDonald Observatory
1971 September

1. Prefatory Note

Laser ranging to the moon promises to provide the means for investigating a number of lunar and terrestrial phenomena to a much higher precision than has been heretofore possible. The interesting lunar problems can be pursued with data from any one or more observatories, although restriction to a single facility does introduce the hazard of local bias in the solutions due to unrecognized systematic errors in the observations. In contrast, very little can be accomplished in earth physics studies using range data from a single observatory. It is imperative to the effective use of these data that there exist a viable means for their distribution or exchange in a sufficiently complete and readily usable form.

This problem was first addressed during COSPAR XIII, when the Chairman of Working Group 1 directed that the present report be prepared. At the same time, a Working Party on Lunar Laser Ranging was formed within the Working Group. Subsequently, the Working Party was endorsed by both IAU and IUGG, and the membership was enlarged to include their representatives.

In an unrelated sequence of events beginning in 1964, IAU Commission 4 established a Working Group on Ephemerides for Space Research. This body served as the inspiration for an informal working group, founded in 1967, which provided working-level communication and coordination in ephemeris research within the USA. This latter group met on numerous occasions during 1967-1969. In addition to providing for standard test cases for areas of desirable duplication of effort, and direct exchange of data and software to reduce unnecessary duplication, this informal group produced two results of some interest to the present discussion. First, the transmission of data was facilitated by adoption by the participants of standard 80-column punched card formats¹. Second, the three US members of the IAU Working Group were asked to carry back to that body certain recommendations concerning international exchange of astrometric and ephemeral data. This was at least a contributing factor in the establishment last year of the IAU Information Bureau on Astronomical Ephemerides, to provide information on the existence and availability of such data. COSPAR Working Group 1 will be represented in the membership of the Bureau.

¹ O'Handley, D. A. "Card Format for Optical and Radar Planetary Data" Jet Propulsion Laboratory Tech. Rpt. 32-1296. Pasadena, 1968.

This report is based on the premise that these two lines of development towards international cooperation and exchange represent two convergent aspects of the same problem, and must be treated as complementary.

The author is pleased to acknowledge the helpful suggestions of many of his colleagues in the preparation of this report. This effort was funded by the National Aeronautics and Space Administration, under Grant No. NGR 44-012-219.

2. Philosophy of the Proposed Standards

We desire to establish some minimum criteria for the permanent recording, cataloguing, and transmission of the laser ranging data. This requires a somewhat different, more comprehensive approach to data recording and preservation than has frequently been the case in the past. The signal generation and detection devices, combined with the level of precision attainable in the observations, dictate that more parameters be preserved. It is also important to avoid crucial ambiguities. For example, the observations are time delays. Does the time delay clock run at the same rate as the clock that measures the epoch of observation? Both rates are necessary for application of the data. By presenting standards for data documentation, we do not propose to specify exactly what information is to be recorded, nor in what way to do the recording, but rather to state *minimum* guidelines for what data seem to be required to insure that the laser measures can be made to satisfy their enormous potential.

In addition to the general documentation criteria, we propose some very specific standards for the transmission of data between institutions or their deposition in public data centers. The need for machine-readable formats seems self-evident. Efficient use of machine-readable data from various sources requires the establishment of uniform standards insofar as this is possible. Since a similar exercise has been undertaken for optical and radar observations, it seems unreasonable to pursue the present goal *ab initio*. We propose, therefore, to maximize the compatibility of our data transmission formats with those of O'Handley². It is to be hoped that these formats will provide the basis for a more comprehensive codification by the Information Bureau on Astronomical Ephemerides.

We have already implied that there should exist multiple classifications of data standards, since complete archival documentation is not customarily necessary to or desired by the user of astrometric data. It seems to be convenient to discriminate three categories, to be described in detail in subsequent sections of this report. The categories can be considered as approximating the functions of journal publication, public deposition, and archive data, respectively. These represent three levels of detail, corresponding to different purposes to which the data may be applied.

In their present form, these proposals are intended as first-order approximations, evolved from experience within the laser program and from the discussions held within Working Group 1 during the 14th Plenary Meeting. As further experience is gained, some modifications will surely follow.

² op. cit.

3. Reduced Data Set

The "reduced data set" will consist of sufficient information to satisfy the requirements of non-critical application, such data as one might publish in a scientific journal. The items recommended for inclusion are:

- Epoch of observation, and its meaning;
- Observed time delay, modified by corrections for geometric and electronic calibration delays and for the atmospheric refraction delay;
- System time delay resolution;
- Telescope and reflector identification;
- Time base identification for both epoch and time delay.

These data, which are certainly adequate for many purposes, are easily accommodated on a standard 80-column punched card. A proposed card format is specified in Appendix C.

4. Astrometric Data Set

This category is of most critical interest from the standpoint of serious application of the data, and it represents those data which we propose should constitute the standard grouping for deposition in a public data center or publication comparable to observatory annals. Here we must distinguish between data provided for each observation and other data recorded at most once for each run, but which are needed for high-confidence use of the data:

Each observation

- Epoch of observation, and its meaning;
- Observed time delay, unaffected by any corrections;
- Observational uncertainty, with a description of its basis;
- Gravimetric data (*)
- Telescope and reflector identification;
- Time base identification for both epoch and time delay.

Each run

- Clock calibration data;
- Electronic and geometric calibration delays to be subtracted from the observation;
- Atmospheric data (temperature, pressure, humidity, seeing, wind speed);
- Laser parameters (energy, pulse length, frequency);
- Detector parameters (count rates, inherent resolution, range gate structure);
- Number of shots per run.

Once

- Station description;
- Nominal telescope coordinates;
- Precise separations between transmitter and receiver, if appropriate;
- Relation of primary mirror position to fixed reference point.

* The measurement of relative gravimetric data is considered desirable for those locations for which a simple analytic model is not adequate to account for solid earth tides.

A separation can be based on considerations of application. Customarily, use of the data to nanosecond accuracy requires only certain of these data. A conventional card format is proposed for these data in Appendix C. The other items permit either finer-scale reduction of the observations or re-evaluation of confidence levels and uncertainty estimates. A second machine-readable format is proposed for these data. The principal virtue claimed for these formats is that we propose immediately to begin using them in transmissions of lunar ranging data from the McDonald Observatory.

5. System Data Set

Each of the data-taking organizations will wish to maintain its own archive files, basically observatory logs, which will contain all of the information contained in the "astrometric data set" for that observatory, but also such additional items as might be useful in evaluating system performance. This might include such parameters as laser beam divergence, spatial and spectral filter width, filter/laser wavelength matching, etc. This seems to be a purely local matter of little impact on the astrometric use of the time delays, and thus this category does not lie within the scope of the present report. One will note that the McDonald formats (Appendix C) will include some of these items.

6. Distribution Mechanisms

Central to the entire purpose of this report is the precept that full utilization of these astrometric data of unprecedented precision can only occur if the data are made conveniently available outside the originating organization, indeed outside the country of origin. It may be admitted that each observing group may wish to restrict access to their own data for some specified time. It is further understood that, particularly in the early stages of an observational program, the observational identification problem (noise filtering) may not permit adherence to intended distribution schedules. Nonetheless, it seems unambiguous and unarguable that some mechanism for general and open distribution of the data need be endorsed in principle and, insofar as possible, adhered to in practice.

COSPAR has provided for open repositories of space science data in the network of World Data Centers, whose charter includes the handling of "precise positional observations... of great scientific value." There can be no question that the laser observations satisfy this description. We propose that Working Group 1 urge the WDC's to accept the responsibility of serving as a focal point for the dissemination of these data. We further propose that all lunar laser ranging facilities in countries whose National Scientific Institutions adhere to COSPAR be urged to agree to submit their observations, in the form of astrometric data sets, either to the WDC's directly or to national data centers that exercise free exchange with the WDC's (e.g. the US National Space Science Data Center). Each group should also be free to make other distribution arrangements as well, including access to reduced data sets or system data sets as they see fit.

In addition to making explicit distribution arrangements, the observing organizations should be urged to register these arrangements with the IAU Information Bureau on Astronomical Ephemerides, for the convenience of those scientists unfamiliar with the COSPAR organization. It is presumed that the COSPAR representatives in the Information Bureau organization will provide coordination between the function of the Bureau and the wishes of COSPAR Working Group 1. Dr. Veis has also suggested that the COSPAR/IUGG Central Bureau for Satellite Geodesy be kept informed of available data.

Appendix A

Notes on Selected Data Items

Epoch of observation

Systems may be designed with either the transmission time or the reception time as the epoch reference. In every case, the appropriate option must be explicitly available. In addition, if reception time is used, this must be *observed* reception time, rather than predicted.

Observational uncertainty

This parameter is somewhat subjective and, for a given observation, may be revised *ex post facto*. Its minimum value is the shot-by-shot resolution, but may be much higher if electronic or other operating problems exist in the observing system.

Electronic delay

This represents the time delay in the detection circuitry, which does not relate to a distance.

Geometric delay

The observations will need to be reduced to a point in the light path fixed relative to the telescope pier. The geometric calibration delay represents the total light path from that point to the front face of the laser, plus the total light path from the fixed point to the detector. For bistatic operation, a fixed point reference is required separately for receiver and transmitter.

Nominal telescope coordinates

These should refer to the fixed point(s) described above. The nominal coordinates should be (as nearly as practical) the best available estimate of the coordinates relative to the Earth's center of mass, along with a description of the method of determination. Spherical coordinates are to be preferred to rectangular. Astronomical coordinates (including radial distance) may be given if more appropriate data are not available.

Primary mirror

Some telescope designs require the primary mirror to describe some space path relative to a fixed point such as the intersection of the rotation axes. High-accuracy discussion of observations from such telescopes will require that such motion be taken into account.

Appendix B

Proposed Standard Codes and Units

Epoch of observation

The standard unit is the Julian Date, with decimal fraction.

Observed time delay

The standard unit is the second.

Observational uncertainty

The standard unit is the nanosecond.

Electronic and geometric delays

The standard unit is the nanosecond.

Telescope identification

This will consist of three distinct codes: one for the observatory, one to indicate whether the system uses a single telescope or separate transmitter and receiver, and a third to identify distinct telescope locations in case different arrangements have been used at a single site. The total code requires five digits.

For the basic observatory code, we propose adherence to the established three-digit code used by the IAU Minor Planet Center. The center is willing to assign codes to presently unlisted observatories in a fashion consistent with past practice.

The number of telescopes used could serve as a one-digit code by itself, but we find it convenient from external considerations to propose that a one-digit code distinguish two characteristics. The fourth digit of the observatory code specifies either a single telescope (monostatic) operation or separate transmitter and receiver (bistatic) operation, and it also specifies if the epoch refers to transmission or reception time, according to the following table:

	Monostatic	Bistatic
Transmit	1	2
Receive	3	4

Finally, each observatory will be responsible for assigning a one-digit code (0-9), the fifth digit of the observatory code, specifying distinct sites on the premises. One may note that a changeover from monostatic to bistatic operations need not affect this digit, as that change may be accommodated unambiguously by the preceding digit code.

Reflector identification

A one-digit code should suffice for this parameter, with the digits assigned in the order of emplacement, as follows

- 0 - Apollo 11 (Tranquility Base)
- 1 - Luna 17 (Imbrium)
- 2 - Apollo 14 (Fra Mauro)
- 3 - Apollo 15 (Hadley)

Other numbers will be assigned as new reflectors are activated.

Time base identification

We assume that observation epoch will always be referred to a time base available in real time, regardless of the nature of the observation. The system UTO is included for the sake of generality, even though one does not expect it to be used for laser observations. The time delay will always be based on an oscillator frequency, but we must allow for the possibility of a non-standard frequency. The proposed codes are

- 0 - UTO
- 1 - UTC
- 2 - A.1 (USNO)
- 3 - AT (BIH)
- 4 - USSR atomic time
- 9 - non-standard frequency

Clock calibration

The standard units are microseconds (epoch) and hertz (frequency)

Atmospheric data

The standard units are: for temperature, Celsius degrees
for pressure, millibars
for humidity, % saturation
for seeing, arc seconds
for wind speed, km/hour

For the present purpose, no distinction need be made between 99 % and 100 % humidity.

Laser parameters

The standard units are joules (energy) and nanoseconds (pulse length) full width between the half-power points.

Telescope coordinates

The standard units are: for radial distance, km
for longitude, degrees *east*
for latitude, degrees north
for rectangular coordinates, km

Appendix C

Proposed Standard Punched Card Formats

Standard formats are presented below for the transmission of reduced and astrometric laser data via 80-column punched cards. Some of the details of the formatting were chosen for compatibility with present usage of other data familiar to the author. This is particularly true of the placement and field size of certain data, such as body identifier, epoch, and observatory code.

Reduced data card

Col. 1: = P (11-7 punch)
2-4: = 011 (Body identifier)
5-21: Epoch of observation (Julian date with 10 decimal digit fraction, decimal implied following col. 11)
22-26: Observatory code
27: Blank (not used)
28: Reflector code
29: = L (11-3 punch, observation type)
30: Epoch time base
31-42: Two-way time delay (seconds, decimal implied following col. 32, 10 decimal digit fraction)
43-47: Observational precision estimate (nanoseconds, decimal implied following col. 46)
48-53: Refraction delay removed from observation
54-56: Blank (not used)
57-58: = -1 (identifies reduced data)
59-62: Blank (not used)
62-66: Frequency offset of time delay clock from nominal rate. If Col. 67 = 9, offset is from A^T (parts in 10'')
67: Time delay time base
68-72: Blank (not used)
73-80: Year, month, day

Astrometric data card

Col. 1-47: Identical with reduced format
48-53: Electronic delay (nanoseconds, decimal implied following col. 52)
54-58: Geometric delay (nanoseconds, decimal implied following col. 57)
59-67: Identical with reduced format
68-72: Atmospheric pressure (mbars, decimal implied after col. 71)
73-80: Identical with reduced format

Operational environment data card

Col. 1: = Z (0-9 punch)
2-4: Observatory code (first 3 digits)
5-14: Julian date beginning run (truncated to 3 decimal digits, decimal implied following col. 11)
15: Blank (not used)
16-22: Clock epoch offset (μ sec) to be added to clock reading
23-25: Temperature ($^{\circ}$ C)
26-27: Humidity (% saturation)
28-29: Wind speed (km/hr)
30-31: Seeing (0.1 arc sec)
32-34: Blank (not used)
35-37: laser energy (0.1 joule)

Col. 38-42: laser frequency (10^{10} Hz)
43-45: pulse length (0.1 nanosec)
46-48: resolution (0.1 nanosec)
49-51: photomultiplier dark count (kHz)
52-54: Moon count rate (kHz)
55-57: Star count rate (kHz)
58-62: Calibration star identification
63-65: Filter spectral width (0.1 Å)
66-68: Filter spatial width (0.1 arc sec)
69-72: Number of shots this run
73-80: Year, month, day

University of Texas at Austin
Research Memorandum in Astronomy
1981 October

I. Introduction

Not only is the laser ranging experiment capable of rendering significant improvements to a large number of fundamental physical constants and solar system parameters, it is also possible to apply the data to study the Earth itself. However, in order that lunar laser ranging data be used to its fullest capacity it is necessary that it be made available to the scientific community in a standard, useable form with sufficient environmental and systemic description included to assure proper reduction of that data. It is unreasonable to assume that all observing stations will be identical in their hardware and software configurations; further, it is impossible to assess and reduce in real-time all relevant environmental and systemic parameters during routine observing. Thus it has been assumed that such observatory-unique "raw" data be transmitted to a central agency in order to filter signal photons from the noise, form normal points from logical sub-sets of signal returns, and, perhaps most importantly, consolidate range, environmental, and systemic information into a standard form to be made available to the general scientific community.

In August of 1980 the McDonald Observatory Lunar Laser Ranging Station completed eleven years of operations using the 2.7m reflector. During that entire period of time LLR observations were obtained in a routine manner. The University of Texas at Austin has been responsible for the routine filtering, compression, and distribution of that data since mid-1971. Archival deposits of those data have been made periodically into the National Space Science Data Center (and the World Data Center) which is maintained at the NASA Goddard Space Flight Center in Greenbelt, Maryland (USA). These McDonald observations now comprise the bulk of all available LLR information. As we continue with our second decade of activity in this experiment, we have continued and will continue to maintain a steady and timely flow of data into the general scientific community. The present report comprises the documentation to be used in conjunction with the 1981 October deposit into the NSSDC which

contains normal points, filtered observations and unfiltered photon stops for the months January through June, 1981. Note that data deposits in this series continue to be made semi-annually in the spring and fall and consist of 6-month blocks of data which end three months before the deposit date, i.e., January-June or July-December.

A microfiche copy of the January-June, 1981 McDonald Observatory LLR data set has been included at the back of this report. Also, the interested reader is referred to Appendices C and D. Appendix C is entitled "Lunar Laser Calibration Data"; Appendix D is entitled "McDonald Lunar Laser Operations Log". Both of these appendices include information in a format similar to that which had been included in the tri-annual reports issued by E. C. Silverberg under NASA Grant NGR 44-012-165. With the demise of that grant and because of the different report requirements of the present McDonald Observatory Laser Operations Contract, this type of information is presently being included in our semi-annual NSSDC LLR data deposits.

A detailed overview of the equipment used to acquire the data described in this document has been provided by E. Silverberg (1974) and the precise role played by telescope mirror geometry and its effect upon the proper reduction of the data is discussed by Shelus et al (1975). New, definitive geometric calibration information for the entire McDonald 2.7m LLR data set can be found in Appendix A of this document. The interested user is also directed to papers by Mulholland (1980a, 1980b) and by Ferrari et al (1980) for current information and a near-exhaustive bibliography regarding most phases of the LLR experiment. Finally, a summary of the statistics concerning the first ten years of McDonald Observatory LLR operations has been compiled by Shelus (1980) and can be obtained from the author upon request.

II. Observational Statistics

The 119 McDonald Observatory LLR normal points contained in this data deposit represent some 957 individual photon returns from the moon. The distribution of the data with respect to month and to reflector is presented

	I	I	I	I	I	I	I	TOTALS

Table I. Summary of filtered observations by month and by reflector.

in Table 1. The statistics on the number of photons per normal point can be found in Figure 1. Figure 2 presents the current normal point distribution with respect to the classical fundamental arguments of the lunar motion. Figure 3 gives similar information with respect to the lunar declination and the local hour angle. Finally, Figure 4 presents statistics on uncertainty estimates for this data set. It should be noted that the various statistical information for the present data is essentially identical to earlier deposits in this series.

III. Data Description

The data are contained on three files of a binary magnetic tape written in card-image format, using a CDC Dual Cyber 170/750. It is written with odd parity at 800 bpi. Three types of cards are present, distinguished by an alphabet character in column 1. The letter "Z" designates a "RUN" card, giving environmental and operational parameters for a series of shots. Except for clock epoch offset, these will not customarily be required for application of the range data, but serve to provide information on the observing conditions and the state of the equipment. The letter "P" in column 1 represents a "SHOT" card, containing the result of a single laser firing. The letter "N" in column 1 represents a "NORMAL POINT" card containing the information compressed from an entire "RUN". A word of warning is in order to the unwary user. Some of the specified data may not be available. In the card images, a blank field is a "no information" indicator. Actual null values will be represented by zero punches. The complete "Z", "P", and "N" card formats are as follows:

```

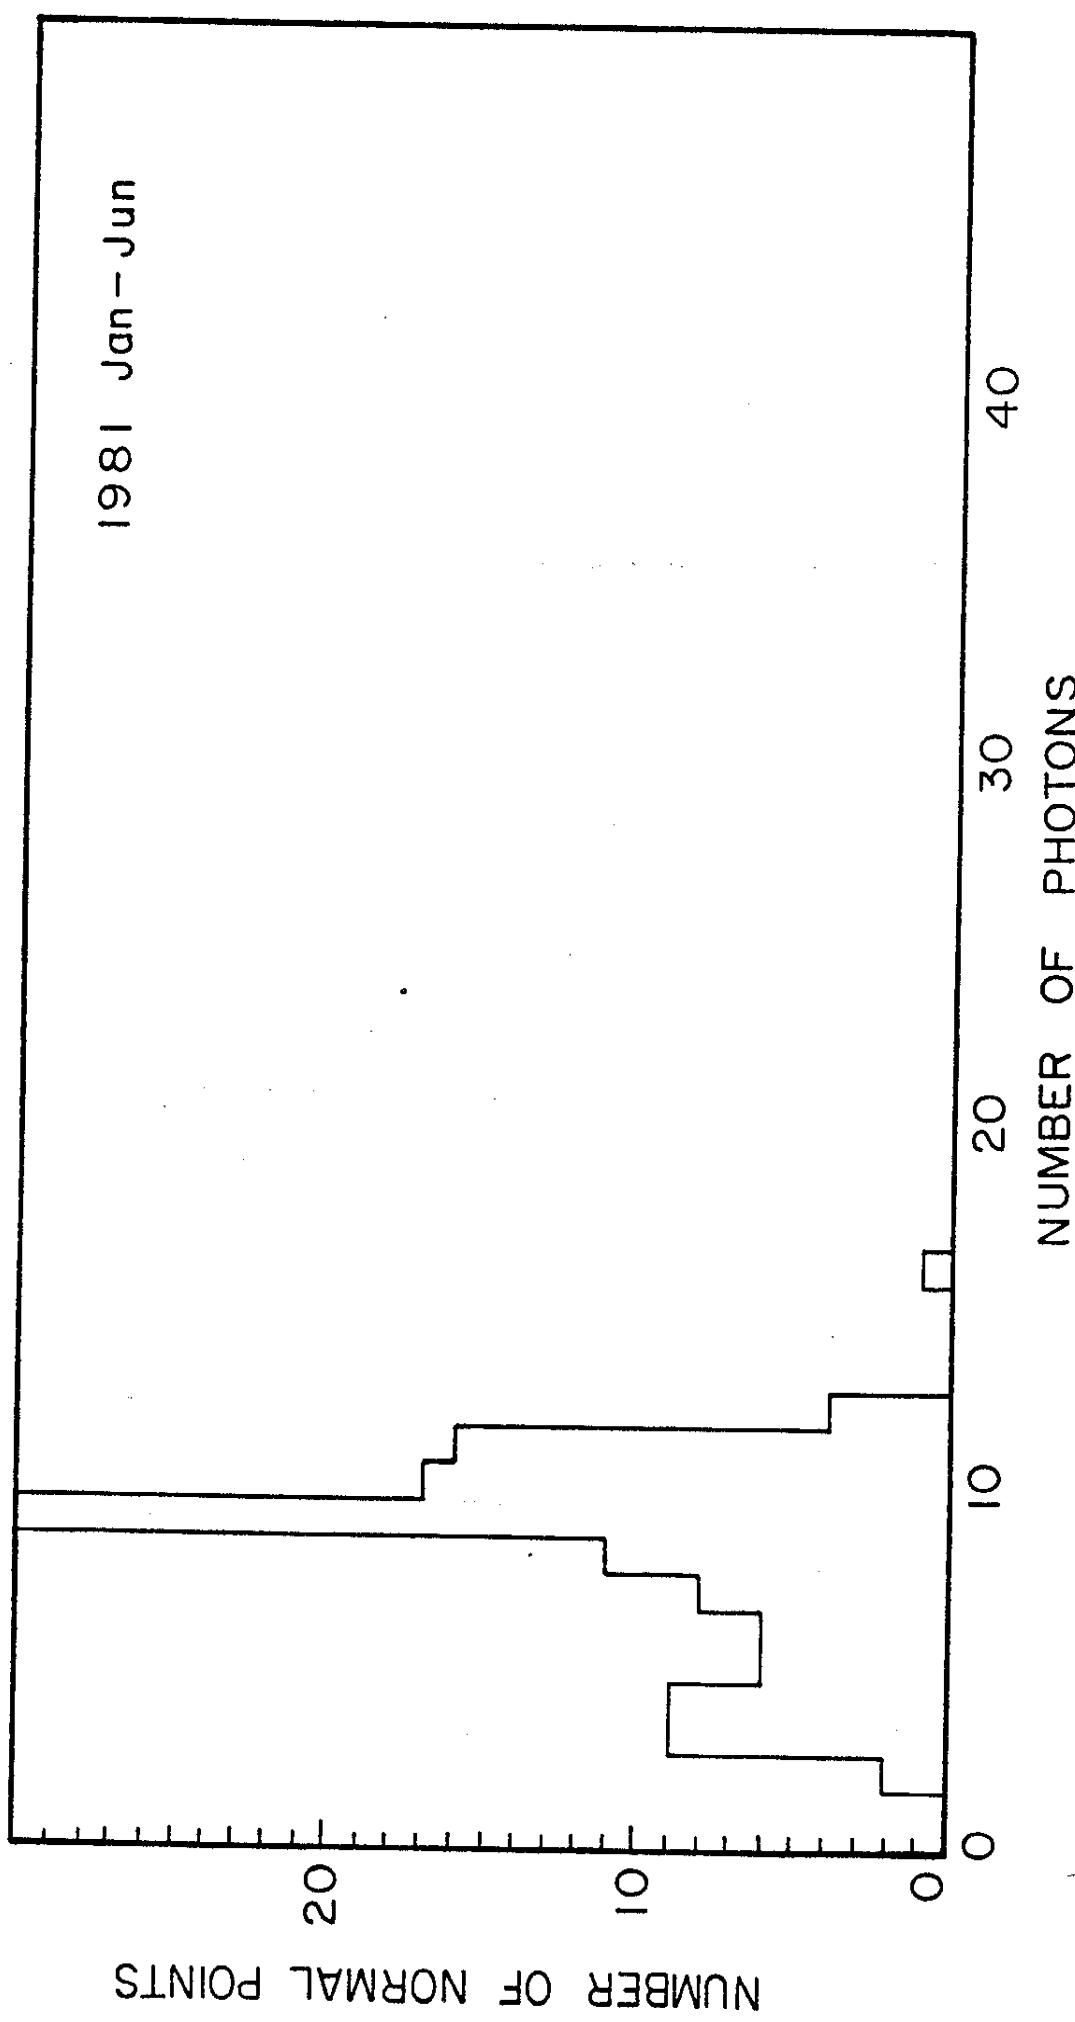

INTEGER ZIN(23)
READ(5,1)ZIN
1 FORMAT(A1,I3,I10,I8,I3,3I2,A1,2X,I3,I5,5I3,A5,2I3,2I4,2I2)

```

For illustrative purposes and in order to define terminology to be used later we shall herein cite our treatment of McDonald Observatory lunar laser ranging data. Due to the fact that the McDonald Observatory obtains its lunar laser ranging observations with the 2.7 m telescope atop Mt. Locke, an instrument which is in regular and continuous use as a normal astronomical telescope, it is necessary that laser runs be scheduled in amongst other projects on-going through any lunar day. Note that by lunar day we refer to that period of time when the Moon is above the horizon at a given observatory, a definition quite analogous to the definition of a solar day. Such a scheduling has resulted in the formation of three laser observing sessions during the course of a lunar day. These three sessions at McDonald are each typically 45^m in length and are held nominally when the Moon is 3^h east of, on, and 3^h west of, the meridian. Of course day to day weather, equipment, and scheduling problems result in varying the length of such sessions and the location of the Moon with respect to the meridian during those sessions.

In the present format, during an observing session, consecutive laser firings are first made at the most favorably placed lunar surface retro-reflector until a sufficient number of returns are obtained to produce a normal point of the desired accuracy. For example, with its present configuration, the McDonald system can produce data to form a normal point with an accuracy of 7-10 cm with about 15 signal returns. Under good conditions these returns can be accumulated with 300-500 laser firings. Such consecutive laser firings at the same reflector, to form a single normal point, are referred to as a run. The observing crew will then set up on the next most favorably placed reflector and repeat the normal point formation

process. Ideally an observing session will produce a normal point for each available lunar retroreflector and then obtain a second normal point of the most favorably placed reflector to complete the cycle. The nominal 45^m observing session is completed by the taking and recording of all relevant environmental and systemic parameters.

The laser observing process does not result in directly useable range data, because the detection system cannot discriminate the source of an arriving photon. It is only the high potential accuracy of the laser system which permits the isolation of the observation from the noise. This requires elaborate computer processing incorporating a statistical filter (see Abbot et al. 1973). To emphasize the need for normal point development, note that through the present epoch, we have formed about 3,000 normal points from McDonald observations alone. Since, on the average, 10-15 photons go into each normal point we are dealing with in excess of 30,000 individual photons. Doing rigorous analysis with this sort of data at the individual photon level would increase computing and analysis costs by a factor of 10 with no significant increase in information content.

The first data file of this deposit contains the signal photon detections which have been compressed into normal points by the procedure referred to above developed at the University of Texas at Austin (Abbot et al, 1973). Each normal point represents the information content of an entire run. Such a normal point observation is comprised of a single pair of "Z" and "N" punched cards.

The second data file contains the photon detections which have been obtained by a data filtering procedure also developed at the University of Texas at Austin (Abbot et al, 1973). This process is based on the assumption of the linearity of (O-C) residuals over a relatively short interval of time and relies on Poisson statistics for establishing a level of confidence in a collection identified by the filter. Application of the process results in the identification of the observations during the subject interval. The

potential user should be aware that the laser cannot be relied upon to produce a simple pulse shape. There sometimes is a complex and/or biased structure within the pulse. Therefore, residuals derived from the signal photons are not necessarily expected to show a Gaussian distribution. The uncertainties assigned are based on the sum of the 1-sigma pulse-width and the measured uncertainty in calibrating the electronic system. Beginning with the April-May, 1972 lunation, a letter code appears in column 32 (formerly unused) of the "Z" card image which provides an estimate for the accuracy of the electronic calibration correction (see Appendix B). The data comprising an observation run consists of a single "z" card and several "p" cards (1 per identified observation).

The third data file contains the unfiltered photon stops. It is most important that the potential user observe the designation "unfiltered". By this, we mean that the real data are heavily interspersed with noise photons from any of the various sources of stray light. Any attempt to use these data in a simple Gaussian application would probably result in a solution closely adhering to the prediction ephemeris which was used to control the detector range gating. Some filtering process needs to be applied to these data before effective use can be made of them. The unfiltered data may be of direct utility or interest to those potential users who may wish to replace our filter criteria with their own. Similar to the shot-by-shot information the data comprising an observation run consists of a single "z" card and several "p" cards (1 per photomultiplier stop).

IV. Acknowledgements

This report and the data tape described herein were prepared at the University of Texas at Austin under NASA Contract NAS5-25948. The observations are obtained at McDonald Observatory under the same contract using predictions computed at the Jet Propulsion Laboratory.

Appendix A

At the present time the geometric calibration constant for the McDonald Observatory Lunar Laser Ranging Data set is usually applied in two stages by most LLR data analysts. The first phase is the 117.2 ns or the 100.4 ns which is contained on the actual data card image. The second phase is the 120.6 ns which was presented by Shelus et al (1975) to account for the 2.7 meter telescope folded light path. Definitive calibration measurements have recently been made (Silverberg memo follows). As the Silverberg memo states "... All laser range measurements should be referred to that range which would be observed if you used an infinitesimally small instrument placed at the first non-moving point along the receive path ... All McDonald data should be uniformly corrected by the difference between the constants you are using and these newer values ...".

For the sake of consistancy we are continuing to provide the geometrical calibration constant for the McDonald 2.7 meter system as 100.4 ns and are making the user responsible for applying the proper correction from the Silverberg memo. A suggestion to the user is to simply apply a "telescope" correction of 121.8 ns instead of the 120.6 ns value which is quoted in the referenced Astronomical Journal paper, i.e., Shelus et al (1975). That a proper geometrical calibration constant be applied to the McDonald LLR data set is especially important when multi-station and multi-technique experiments are being attempted.

At this time we also draw attention to paragraph 3 of the Silverberg memo which presents the measured offsets from the 2.7 meter telescope axis intersection to the NGS survey marker on the dome floor.

MEMORANDUM

To: All Lunar Range Users, c/o Peter Shelus

From: E.C. Silverberg

Subject: McDonald Calibration Data

With the help of an NGS Field Team we have finally determined definitive calibrations for the McDonald lunar range data. Since 1973 we have been using a geometrically constant system; but one which was uncertain by as much as 2-3 nanoseconds in the overall range bias. This uncertainty has been greatly reduced by our recent work. Additional data has also been added to relate the 2.7 meter axes to the NGS survey mark on the telescope pier.

All laser range measurements should be referred to that range which would be observed if you used an infinitesimally small instrument placed at the first non-moving point along the receive path. The latter is usually the intersection of the telescope axes. Thus, a dynamical solution for station site coordinates will determine the geocentric position of a point on the #4 mirror in the 2.7 meter reflector. The relevant dimensions are given on the next page. A raw McDonald range measurement can be corrected to these conditions by subtracting a value equal to $K - K' + 70.573$ meters or $K - K' + 235.4$ nanoseconds. (The estimated error is about ± 1 cm.) K and K' are observed shot by shot by the feedback calibration system. In the past we have divided this calibration correction into an electrical component, $ELCOR = K - K' + 13.19$ nanoseconds and a geometric component (including the finite telescope size) of $GEOC = 222.2$ nanoseconds (66.621 meters) but the division is somewhat arbitrary. All McDonald data should be uniformly corrected by the difference between the constants you are using and these newer values. (We have always been certain of the relative biases of the various older systems, so any implied change in the last setup pertains to the entire eleven years.)

In addition to determining the system calibration constants we have accurately determined the offset of the 2.7 meter axes from the NGS survey mark on the dome floor. The survey marker is 5.304 meters down, .739 meters north and 0.143 meters east from the 2.7 meter calibration point.

Barring any further discoveries, this should be the last calibration work on the 2.7 meter system. I trust these calculations will lay this area to rest prior to abandoning the instrument sometime next year.

Eric C. Silverberg
Eric C. Silverberg

Relevant Dimensions Used for the Calculations

Primary to Secondary Mirror	= 7.513 meters
Secondary to #3 Mirror	= 6.309 meters
#3 Mirror to #4 Mirror	= 3.039 meters
#4 Mirror to #6 Mirror	= 12.250 meters
#6 Mirror to PMT along the receive path	= 240.875"
#6 Mirror to the start diode behind #6	= 5 "
#6 Mirror to the feedback beam splitter along the receive path	= 195.75"
Feedback beam splitter to PMT along the feedback path	= 45.125"

Therefore: ELCOR, the difference measured if light hits the start diode and PMT simultaneously,

$$\begin{aligned} &= K - K' \text{ (feedback calibration values)} \\ &\quad + 13.19 \text{ nanoseconds} \end{aligned}$$

and

GEOC, the correction to the intersection of telescope axes plus the correction for finite telescope size

$$\begin{aligned} &= 30.491 \text{ meters} + 36.130 \text{ meters (respectively)} \\ &\quad \text{or } 222.2 \text{ nanoseconds} \end{aligned}$$

Appendix B

Code for the accuracy of the McDonald Observatory electronic calibration
correct ion:

- A - better than (+/-)200 picoseconds
- B - (+/-)200 to (+/-)400 picoseconds
- C - (+/-)400 to (+/-)600 picoseconds
- D - (+/-)600 to (+/-)1000 picoseconds
- E - (+/-)1.0 to (+/-)1.5 nanoseconds
- F - (+/-)1.5 to (+/-)2.0 nanoseconds
- G - (+/-)2.0 to (+/-)4.0 nanoseconds
- H - worse than (+/-)4.0 nanoseconds

These calibration codes were established by E. C. Silverberg.

Appendix C

The Lunar Laser Calibration Data

from

1 January 1981 to 30 June 1981

EXPLANATION OF THE CALIBRATION DATA

The following pages contain the calibration constants for the six lunations covered by the present report. Pertinent information concerning the photodetectors and related timing discriminators is presented above the columnar data. The columnar categories are explained below.

A (pulser): This column contains the uncorrected calibration constant for the entire lunar ranging system as measured by an electronic start and a light emitting diode-PMT stop of the TDC-100 timer. Due to differing cable lengths of the start and stop paths in the system, this number is not the magnitude of the actual system calibration value. It is, however, a measure of the relative shift in the calibration value on a day-to-day basis. The units are nanoseconds.

B (laser pulse): This column shows the single shot uncertainty as keyed to the following code: (all values are in nanoseconds)
 $A = \pm 0.4$, $B = \pm 0.5$, $C = \pm 0.6$, $D = \pm 0.7$, $E = \pm 0.8$, $F = \pm 1.0$,
 $G = \pm 1.2$, $H = \pm 1.4$, $I = \pm 1.7$, $J = \pm 2.0$, $K = \pm 2.4$, $L = \pm 2.9$,
 $M = \pm 3.5$, $N = \pm 4.2$. The absence of a letter will indicate the single shot uncertainty of J.

C (feedback): This column gives the arithmetic mean in nanoseconds of the "feedback calibration returns" through the entire ranging system as recorded by the system teletype during actual ranging. A "feedback calibration return" is produced by a start-diode start and a PMT stop of the TDC-100 timer. The uncertainty gives the standard deviation of data points within 5 nsec of the mean.

D (ELCOR): This column shows the value of ELCOR which has been determined by subtracting the nominal value of K' (15.3 nsec) and adding 13.9 nanoseconds (geometrical delay) to the average in column C. The units are tenths-of-nanoseconds. The minus sign was added to coincide with how this additive constant appears on the preliminary data cards. Letters following the numerical value indicate the uncertainty in the determination of ELCOR based on the feedback uncertainty according to the code (all values are in picoseconds):

$$\begin{aligned}0 &\leqq A \leqq \pm 200 \\ \pm 200 &\leqq B \leqq \pm 400 \\ \pm 400 &\leqq C \leqq \pm 600 \\ \pm 600 &\leqq D \leqq \pm 1000 \\ \pm 1000 &\leqq E \leqq \pm 1500.\end{aligned}$$

NOTE: It should be remembered that ELCOR values, as given by these publications, are preliminary estimates determined at the ranging site using simple algorithms. As of March 1976, the final calibration constants, incorporating formal derivations of the calculation uncertainties, have been determined by the data reduction group in Austin, headed by P. Shelus.

Appendix D

The McDonald Lunar Laser Operations Log

from

1 January 1981 to 30 June 1981

EXPLANATION OF THE OPERATIONS LOG

The information presented in the McDonald Lunar Laser Operations Log is as follows:

DATE (column 1): The local calendar date at the start of the day's ranging operation.

LUNAR DAY (column 2): The approximate number of days which have elapsed since the previous new moon. This estimate comes from the American Ephemeris and Nautical Almanac: Ephemeris for Physical Observations of the Moon.

UTC DAY (column 3): The Universal Coordinated Time day of the calendar year as read from the McDonald station clock at the beginning of a range attempt.

TIME (column 4): The UTC hour and minute as read from the station clock at the beginning of a range attempt.

REFL. NO (column 5): The lunar reflector site: 0 = Apollo 11, 1 = Luna 17, 2 = Apollo 14, 3 = Apollo 15, 4 = Luna 21.

RETURNS/SHOT (column 6): The number of lunar returns divided by the number of laser shots fired. Returns are as identified by the laser crew.

SIGNAL LEVEL (column 7): The number of lunar photoelectrons per laser shot for the range attempt. Double photoelectrons are counted as single photoelectron events.

DOUBLES (column 8): The number of returns which were greater than single photoelectron events. Lunar return doubles are presented without parenthesis; noise doubles are presented within parenthesis.

WEATHER (column 9): The general weather conditions at the time of the range attempt.

SEEING (column 10): The guider's estimate of the general seeing conditions in arcseconds, based on stellar or lunar observations.

COMMENTS (column 11): Comments which seem pertinent to the laser crew at the time of ranging.
